### Exercise 1.2

Let W be an  $r \times s$  random matrix, and let A and C be  $n \times r$  and  $n \times s$  matrices of constants. Show that  $\mathbf{E}(AW+C) = A\mathbf{E}(W) + C$ . If B is  $s \times t$  constant matrix, show that  $\mathbf{E}(AWB) = A\mathbf{E}(W)B$ . If s = 1, show that  $\mathbf{Cov}(AW+C) = A\mathbf{Cov}(W)A'$ .

For E(AW + C), by definition  $(AW + C)_{ij} = \sum_{k=1}^{r} A_{ik} W_{kj} + C_{ij}$ . Taking expectations, we have

$$E((AW + C)_{ij}) = \sum_{k=1}^{r} A_{ik} E(W_{kj}) + C_{ij}$$

and we see that this equals  $A\mathbf{E}(W) + C$ .

For E(AWB), E(AWB) = AE(WB) by the above.

## Exercise 1.3

Show that Cov(Y) is nonnegative definite for any random vector Y. Let z be an arbitrary fixed vector with the same length as Y. Then

$$z' \boldsymbol{Cov}(Y)z = z' \boldsymbol{E}[(Y - \mu)(Y - \mu)']z$$
$$= \boldsymbol{E}[z'(Y - \mu)(Y - \mu)'z]$$
$$= \boldsymbol{E}[||z'(Y - \mu)'||^2]$$

and since  $||z'(Y - \mu)'||^2 \ge 0$ , its expectation is also  $\ge 0$ .

### Exercise 1.4

Let M be the ppo onto C(X). Show that (I-M) is the ppo onto  $C(X)^{\perp}$ .

I-M is symmetric and (I-M)(I-M)=I-2M+M=I-M idempotent and thus is a ppo. It projects onto  $C(X)^{\perp}$  because for  $x\in C(X)$ , (I-M)x=x-x=0 and for  $x\in C(X)^{\perp}$ , (I-M)x=x. For the trace,  $\mathbf{tr}(I-M+M)=n$  implies that  $\mathbf{tr}(I-M)+\mathbf{tr}(M)=n$ . Since  $\mathbf{tr}(M)=r(X)$ , we have that  $\mathbf{tr}(I-M)=n-r(X)$ .

### Exercise 1.11

Prove that if  $Y \sim N(\mu, V)$  and VAVBV = 0,  $VAVB\mu = 0$ ,  $VBVA\mu = 0$ , and the conditions from Theorem 1.3.6 hold for Y'AY and Y'BY, then Y'AY and Y'BY are independent.

Let V = QQ' and rewrite  $Y = \mu + QZ$ , where  $Z \sim N(0, I)$ . We now show that the following variables are independent:

$$\begin{bmatrix} Q'AQZ \\ \mu'AQZ \end{bmatrix} \perp \begin{bmatrix} Q'BQZ \\ \mu'BQZ \end{bmatrix} \tag{1}$$

Since these variables are all normal, showing uncorrelatedness shows independence. We first show this for one of the terms.

$$Cov(Q'AQZ, Q'BQZ) = E(Q'AQZZ'Q'B'Q) - E(Q'AQZ)E(Z'Q'B'Q)$$
(2)  
=  $Q'AQQ'B'Q = Q'AVBQ$  (3)

because  $Z \sim N(0, I)$  and QQ' = V. We have from the same argument as the proof of Theorem 1.3.6 in the book that  $Q = Q_1Q_2$ , where  $Q_1$  has orthonormal columns and  $Q_2$  is nonsingular. Thus by the same argument,

$$Q_2^{-1}Q_1'V = Q'$$

Applying this result to Equation 2, we get that

$$Cov(Q'AQZ, Q'BQZ) = Q_2^{-1}Q_1'VAVBV'Q_1Q_2'^{-1} = 0$$

since by assumption VAVABV=0. Similar results hold for the other cross terms.

We then have by the definition of  $Y = \mu + QZ$  that

$$Y'AY = (\mu' + Z'Q')A(QZ + \mu)$$
  
=  $Z'Q'AQZ + Z'Q'A\mu + \mu'AQZ + \mu'A\mu$ 

The second, third, and fourth terms are trivially functions of variables on the left side of Equation 1. The first term is, too, because

$$\begin{split} Z'Q'AQZ &= Z'Q_2^{-1}Q_1'VAVQ_1Q_2'^{-1}Z \\ &= Z'Q_2^{-1}Q_1'VAVAVQ_1Q_2'^{-1}Z \\ &= Z'Q_2^{-1}Q_1'VAQQ'AVQ_1Q_2'^{-1}Z \\ &= Z'Q'VAQQ'AQZ \\ &= (Q'AQZ)'(Q'AQZ) \\ &= ||Q'AQZ||^2 \end{split}$$

is a function of Q'AQZ, where the second line follows from the assumption that VAVAV = VAV from Theorem 1.3.6 in the book. A similar argument holds for Y'BY. Thus Y'AY is a function of variables on the left side of Equation 1, and Y'BY a function of the right side. Since the two sides of Equation 1 are independent, Y'AY and Y'BY are independent.
